Amoeba by zoorik

Built for Azure and AWS

Supported on Windows and Linux

Stop paying for empty disk space.

Amoeba moves a VM's data disks onto one btrfs pool, sized to your data.
Then it rightsizes the pool as your data grows and shrinks.

Reduce cost

The pool is sized to your data, so you pay for close to what you use.

Safe by design

The pool shrinks one disk at a time. A disk leaves only when it is empty.

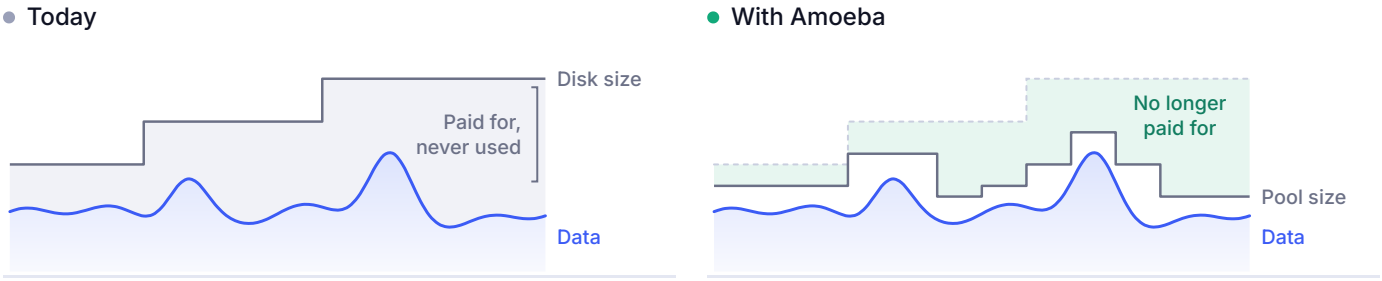

Reliable

No code changes. After the move, the pool grows and shrinks while services run.

Full visibility

You decide which VMs Amoeba manages, and see every change it makes.

Cloud disks only grow. Amoeba's pool grows and shrinks with your data.

Illustrative.

HOW IT WORKS

01

Onboard a VM

Choose each Windows or Linux VM. Amoeba works on its data disks, never the OS disk.

02

Copy as services run

Amoeba copies your data onto one btrfs pool while your services keep running.

03

Switch over

Each mount moves to the pool with a short restart of its services. Each old disk is kept as a snapshot for a few days.

04

Rightsize from then on

The pool grows before it fills. When your data goes down and stays down, the pool shrinks.

Find your own number.

We estimate it takes 50–60% off block storage cost.
It is an estimated range, not a promise.

Run the free assessment on your own VMs. It sends nothing to Zoorik.
